2_가장 큰 수

```python
def solution(numbers):
    answerList = list()
    answer = ''
    for number in numbers :
        answerList.append(((str(number)*4)[:4], len(str(number))))
    answerList.sort(reverse=True)
    for ans in answerList :
        num,length = ans
        answer += num[:length]
        if answer == '0' :
            break
    return answer
```

same algorithm but more elegant code.

```python
def solution(numbers):
    numbers = list(map(str, numbers))
    numbers.sort(key=lambda x: x*3, reverse=True)
    return str(int(''.join(numbers)))
```
